

## Convex Hull

Given a set of points, convex hull is a polygon that encloses all the points.

Points that form the polygon, maximize the area and minimize the circumference.

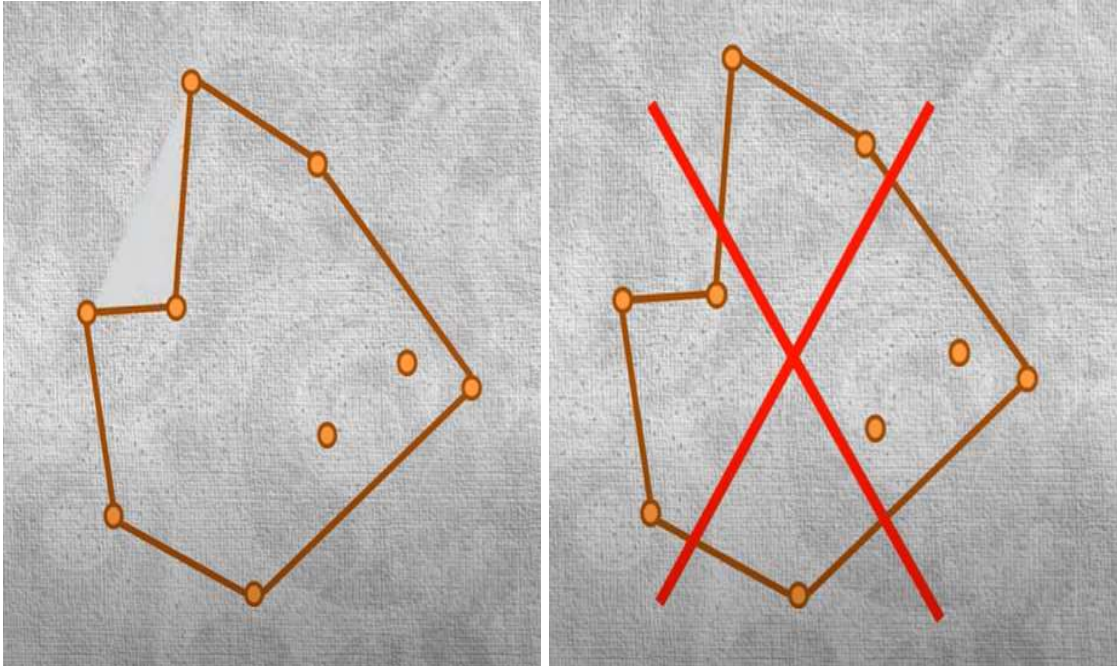

Consider the points given below:

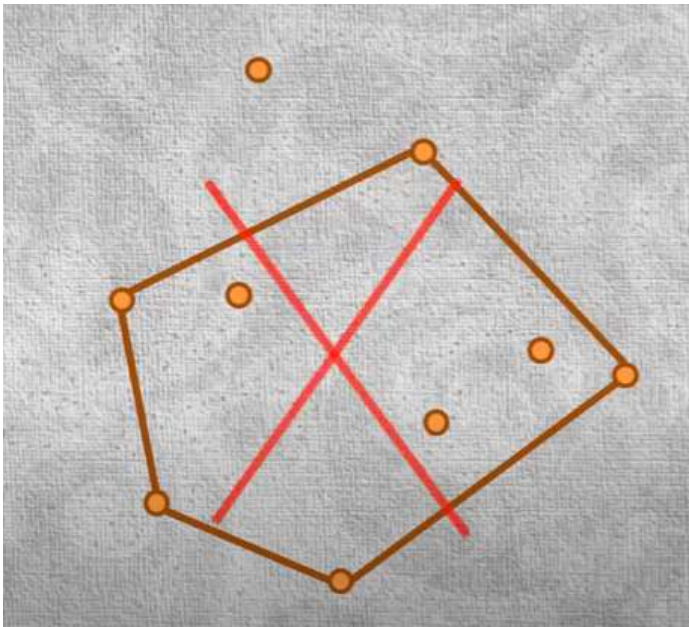

Convex hull of given set of points is as follows:

If some additional points are included, then area of polygon gets reduced and circumference gets increased as shown below:

If any of the points are omitted, then the convex hull (resulting polygon) will not cover all the points.

**Definition:**

The convex hull of a set  $Q$  of points is the smallest convex polygon  $P$  for which each point in  $Q$  is either on the boundary of  $P$  or in its interior.

**Example:****Applications:**

Convex hulls have wide applications in mathematics, statistics, combinatorial optimization, economics, geometric modelling, and ethology.

- Robotics: **Avoiding obstacles**
- Graphics and Vision: **Image and shape analysis**
- Computational geometry: **Many applications**
  - Finding farthest pair of points in a set (Fact. Farthest pair of points are on convex hull.)

**Convex Hull finding algorithms:**

1. Graham's Scan Algorithm
2. Jarvis's March Algorithm (Gift wrapping algorithm)

## Graham's Scan Algorithm:

GRAHAM-SCAN( $Q$ )

- 1 let  $p_0$  be the point in  $Q$  with the minimum  $y$ -coordinate,  
or the leftmost such point in case of a tie
- 2 let  $\langle p_1, p_2, \dots, p_m \rangle$  be the remaining points in  $Q$ ,  
sorted by polar angle in counterclockwise order around  $p_0$   
(if more than one point has the same angle, remove all but  
the one that is farthest from  $p_0$ )
- 3 PUSH( $p_0, S$ )
- 4 PUSH( $p_1, S$ )
- 5 PUSH( $p_2, S$ )
- 6 for  $i \leftarrow 3$  to  $m$
- 7     do while the angle formed by points NEXT-TO-TOP( $S$ ), TOP( $S$ ),  
              and  $p_i$  makes a nonleft turn
- 8         do POP( $S$ )
- 9         PUSH( $p_i, S$ )
- 10 return  $S$

### Example:

Set of points  $Q$  be as follows:

$p_0$  be the point in  $Q$  with the minimum  $y$ -coordinate, or the leftmost such point in case of a tie

$p_1, p_2, \dots, p_m$  be the remaining points in  $Q$ , sorted by polar angle in counter clockwise order around  $p_0$  (if more than one point has the same angle, remove all but the one that is farthest from  $p_0$ ).

PUSH( $p_0$ ,  $S$ )

PUSH( $p_1$ ,  $S$ )

PUSH( $p_2$ ,  $S$ )

For loop begins in the algorithm:

```
for  $i \leftarrow 3$  to  $m$ 
  do while the angle formed by points NEXT-TO-TOP( $S$ ), TOP( $S$ ),
        and  $p_i$  makes a nonleft turn
    do POP( $S$ )
  PUSH( $p_i$ ,  $S$ )
```

$m$  denotes the number of points other than  $p_0$  that remain.

So,  $i$  in for loop can take the values from 3 to 8.

$i = 3$ ; so,  $p_i = p_3 = 3$

Check while loop condition.

It is left turn. Condition is false. While loop terminates.

So, push 3 into stack.

$i = 4$ ; so,  $p_i = p_4 = 4$

Check while loop condition.

It is right turn (nonleft turn). Condition is true. So, pop from stack.

While loop continues.

Check while loop condition.

It is right turn (nonleft turn). Condition is true. So, pop from stack.

While loop continues.

Check while loop condition.

It is left turn. Condition is false. While loop terminates.

So, push 4 into stack.

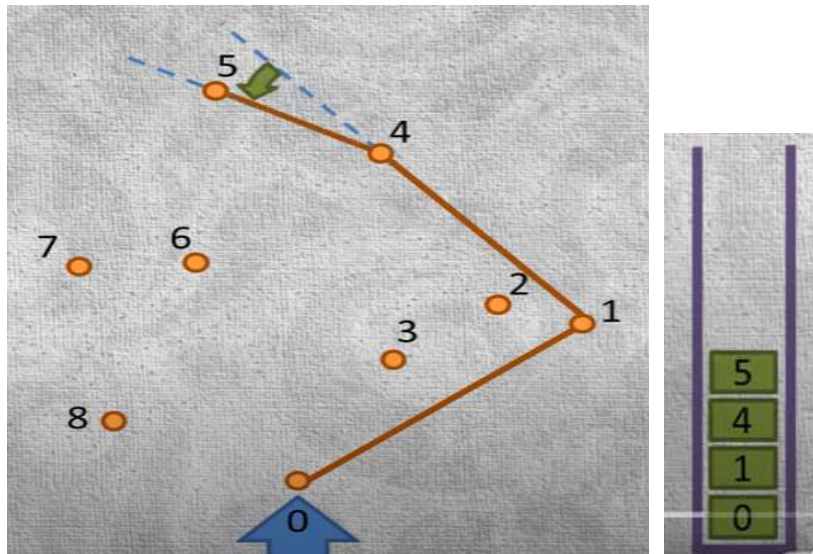

$i = 5$ ; so,  $p_i = p_5 = 5$

Check while loop condition.

It is left turn. Condition is false. While loop terminates.

So, push 5 into stack.

$i = 6$ ; so,  $p_i = p_6 = 6$

Check while loop condition.

It is left turn. Condition is false. While loop terminates.

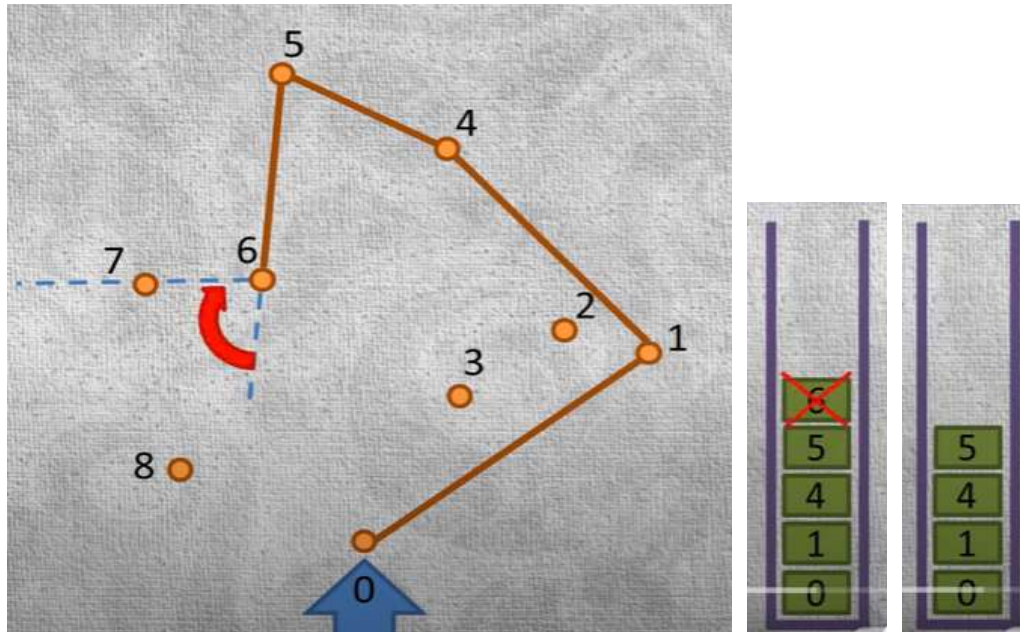

So, push 6 into stack.

$i = 7$ ; so,  $p_i = p_7 = 7$

Check while loop condition.

It is right turn (nonleft turn). Condition is true. So, pop from stack.

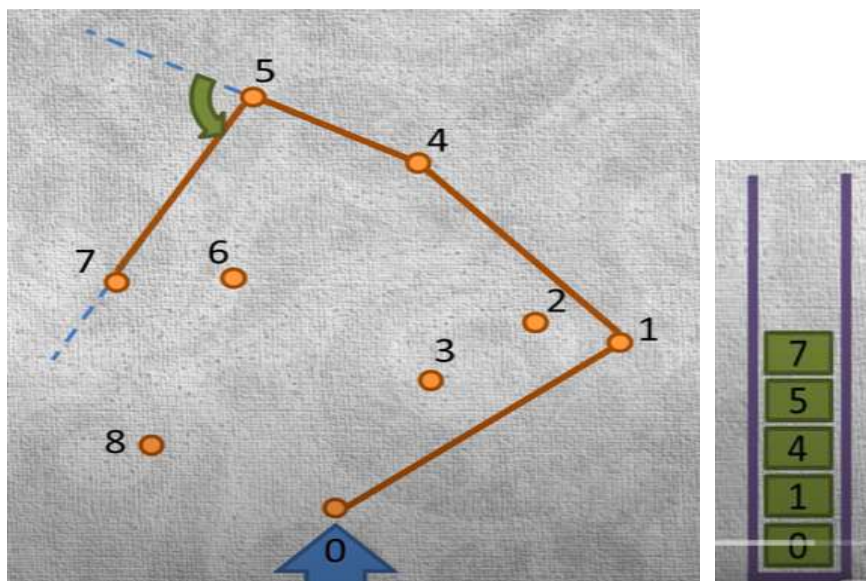

While loop continues.

Check while loop condition.

It is left turn. Condition is false. While loop terminates.

So, push 7 into stack.

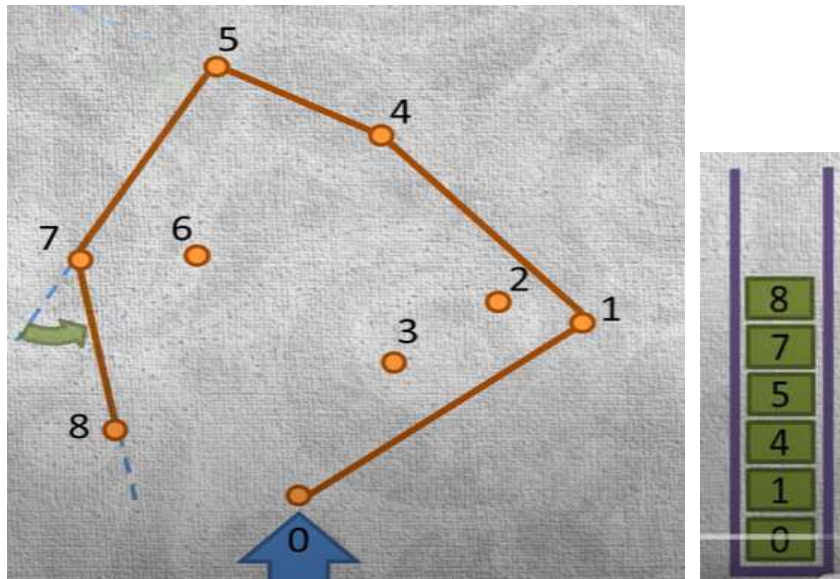

$i = 8$ ; so,  $p_i = p_8 = 8$

Check while loop condition.

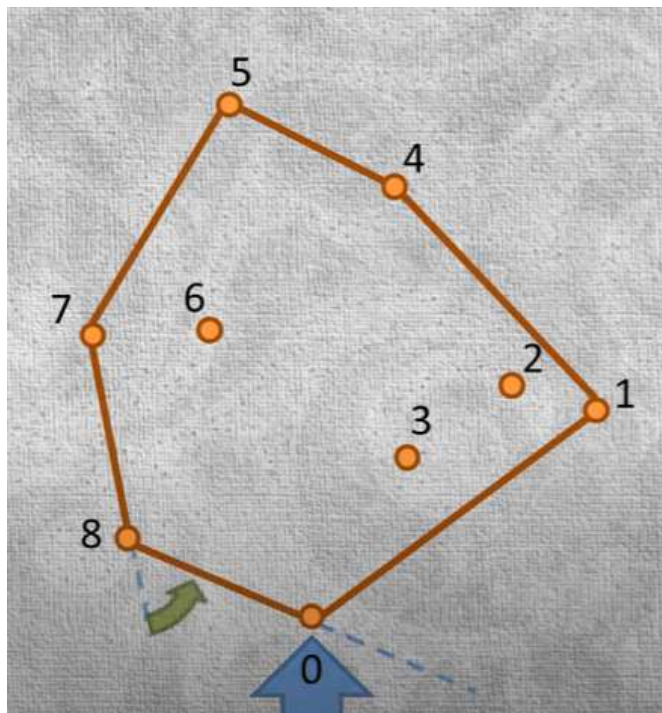

It is left turn. Condition is false. While loop terminates.

So, push 8 into stack.

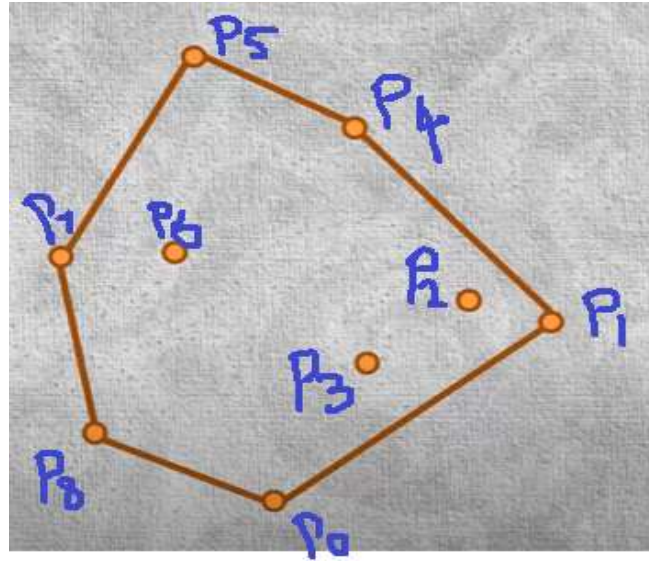

For loop terminates.

With this, we reach the starting point  $p_0$ .

Return S

Solution –  $P_0, P_1, P_4, P_5, P_7, P_8$

### Jarvis's March Algorithm:

Consider the set of points given below:

We start with leftmost point or minimum y-coordinate point in case of a tie.

Here, the leftmost point is  $x_1$ . So, we select  $x_1$ .

Add  $x_1$  to the result

Result =  $x_1$

Point  $x_1$  is on the boundary of polygon.

From  $x_1$ , we have to pick next point such that the next point must be the leftmost point from the  $x_1$ 's perspective.

To determine the next point, try with every possibility (pick every other point i.e. brute force approach) and see which point is the leftmost point from  $x_1$ .

Let us pick  $x_2$ .

Next pick  $x_3$  and ask yourself is  $x_3$  is to the left of the line from  $x_1$  to  $x_2$ .

Yes, it is in the left side.

So, next point is not  $x_2$ . It is  $x_3$ .

Next pick  $x_4$  and ask yourself is  $x_4$  is to the left of the line from  $x_1$  to  $x_3$ .

Yes, it is in the left side.

So next point is not  $x_3$ . It is  $x_4$ .

Next pick  $x_5$  and ask yourself is  $x_5$  is to the left of the line from  $x_1$  to  $x_4$ .

Yes, it is in the left side.

So next point is not  $x_4$ . It is  $x_5$ .

Next pick  $x_6$  and ask yourself is  $x_6$  is to the left of the line from  $x_1$  to  $x_5$ .

No, it is in the right side.

So, we don't consider  $x_6$ .

Similarly,  $x_7$  and  $x_8$  are in the right side of line from  $x_1$  to  $x_5$ . So, we don't consider.

So, after exploring all points, we choose our next point to be  $x_5$  (we make the line permanent).

Add  $x_5$  to the result

Result =  $x_1, x_5$

Point  $x_5$  is on the boundary of the polygon.

Now, repeat same process from  $x_5$ 's perspective. From  $x_5$  face  $x_1$  (First point chosen) and explore all other points.

Let us pick  $x_2$ . It is in the left of  $(x_5, x_1)$ .

Next pick  $x_3$ . It is in the left of  $(x_5, x_2)$ .

So, next point is not  $x_2$ . It is  $x_3$ .

Next, points  $x_4$  and  $x_6$ . They are to the right of  $(x_5, x_3)$ . So, ignore them.

Next  $x_7$ . Point  $x_7$  is on the exact same line of  $(x_5, x_3)$ .

Points which are on the same line are called colinear points.

Farthest point from  $x_5$  is  $x_7$ .

So, our next point is not  $x_3$ . It is  $x_7$ . Point  $x_3$  becomes colinear point.

Next pick  $x_8$ . It is to the right of  $(x_5, x_7)$ . So, ignore.

So, after exploring all points, we choose our next point to be  $x_7$  (we make the line permanent).

Add  $x_7$  to the result. Also, add colinear point  $x_3$  to the result.

Result =  $x_1, x_5, x_3, x_7$

Points  $x_3$  and  $x_7$  is on the boundary of the polygon

Now, repeat same process from  $x_7$ 's perspective. From  $x_7$  face  $x_1$  (First point chosen).

From  $x_7$  face  $x_1$  (First point chosen), explore all other points.

Points  $x_2, x_4, x_6$  are to the right of  $(x_7, x_1)$ . So ignore them.

Point  $x_8$  is to the left of  $(x_7, x_1)$ .

So, after exploring all points, we choose our next point to be  $x_8$  (we make the line permanent).

Add  $x_8$  to the result.

Result =  $x_1, x_5, x_3, x_7, x_8$

Point  $x_8$  is on the boundary of the polygon

Now, repeat same process from  $x_8$ 's perspective. From  $x_8$  face  $x_1$  (First point chosen).

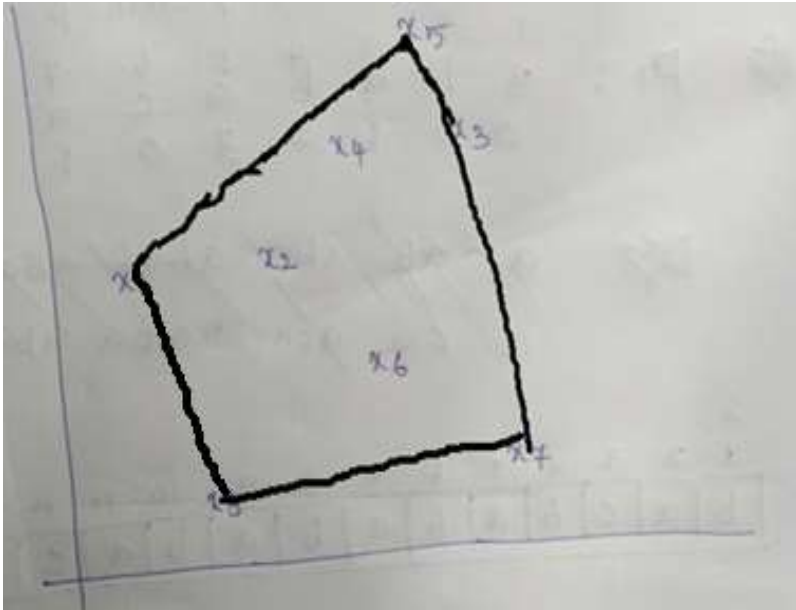

From  $x_8$  face  $x_1$  (First point chosen) and explore all other points.

Points  $x_2, x_4, x_6$  are to the right of  $(x_8, x_1)$ . So ignore them.

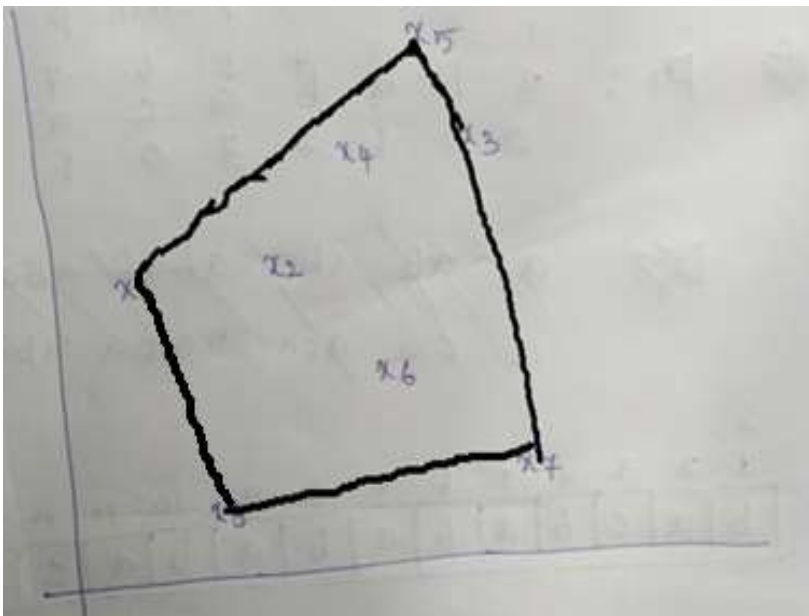

No points lie on the left side.

Now we have reached the starting point  $x_1$  (we make the line permanent).

**Final Result:**

Result =  $x_1, x_5, x_3, x_7, x_8$

### Algorithm:

- 1) Initialize  $p$  as leftmost point.
- 2) Do following while we do not come back to the first (or leftmost) point.
  - a) The next point  $q$  is the point such that the triplet  $(p, q, r)$  is counterclockwise for any other point  $r$ .
  - b)  $\text{next}[p] = q$  (Store  $q$  as next of  $p$  in the output convex hull).
  - c)  $p = q$  (Set  $p$  as  $q$  for next iteration).

### Practice Problem:

Given the following set of points 'P' in a plane. Construct the smallest polygon Q such that each and every point in 'P' is either on the boundary or inside the polygon. Use the algorithm which starts with minimum x coordinate value and keep wrapping the points given below in counter clockwise direction to find the polygon.

(2,1)(3,3)(5,4)(-2,2)(-3,1)(-4,3)(-1,-2)(-3,-4)(2,-3)(4,-4)(1,-4)
